	Software Quality Control to Bugzilla file	Date 02/08/2005

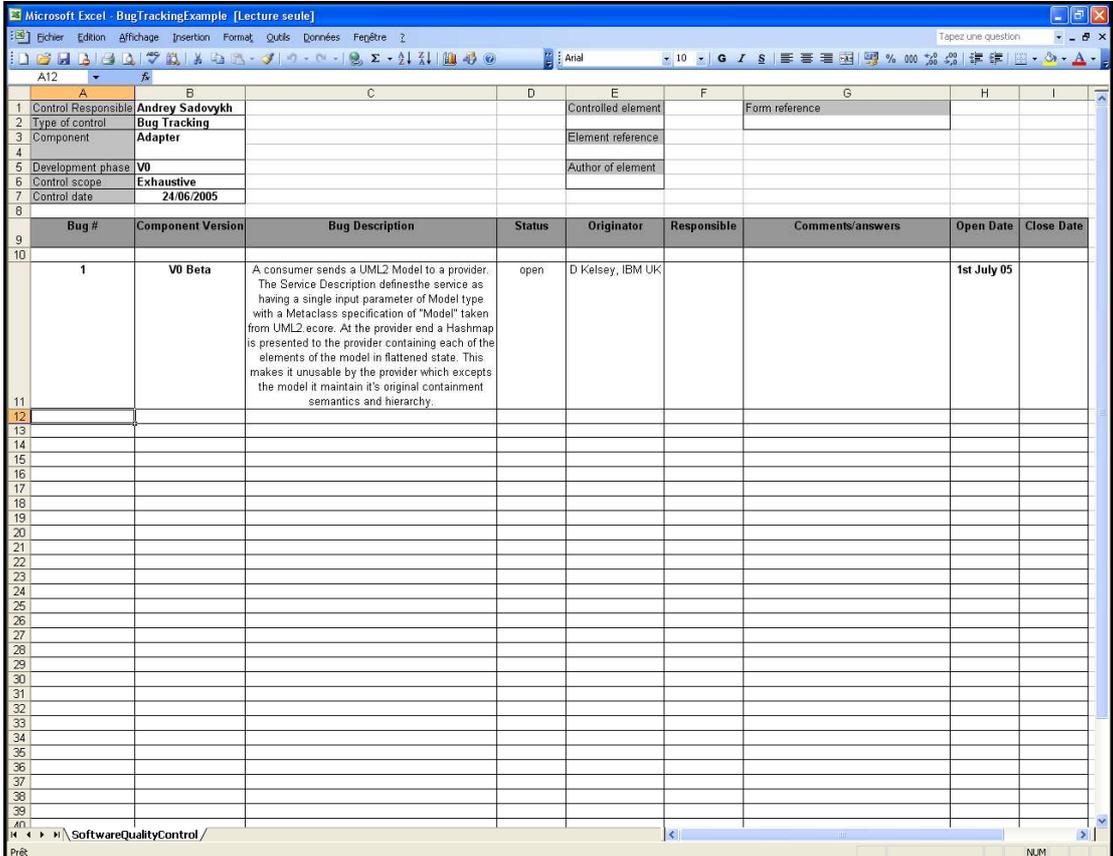

1. ATL Transformation Example

1.1. Example: Software Quality Control → Bugzilla file

The “Software Quality Control to Bugzilla file” example describes a transformation from a SoftwareQualityControl model to a simple Bugzilla XML file. Bugzilla [1] is a free "Defect Tracking System" or "Bug-Tracking System", originally developed by the Mozilla Foundation, which allows individual or groups of developers to keep track of outstanding bugs in their product effectively. The transformation is based on a Software Quality Control metamodel which describes a simple structure to manage software quality controls (and more especially bug-tracking). The input of the transformation is a model which conforms to the SoftwareQualityControl metamodel. The output is an XML file whose content conforms to a simple Bugzilla DTD.

1.1.1. Transformation overview

The aim of this transformation is to generate a valid and well-formed XML file for Bugzilla from a SoftwareQualityControl model. Figure 1 gives an example of a simple Microsoft Office Excel workbook whose content is a particular representation for “bug-tracing” or “bug-tracking” (which is the type of software quality control that interests us for our example). The bugs’ information contained in the single worksheet of this workbook has been previously injected into a SoftwareQualityControl model thanks to the “MicrosoftOfficeExcel2SoftwareQualityControl” transformation (see [2]).

Bug #	Component Version	Bug Description	Status	Originator	Responsible	Comments/answers	Open Date	Close Date
1	V0 Beta	A consumer sends a UML2 Model to a provider. The Service Description defines the service as having a single input parameter of Model type with a Metaclass specification of "Model" taken from UML2.ecore. At the provider end a Hashmap is presented to the provider containing each of the elements of the model in flattened state. This makes it unusable by the provider which expects the model it maintain it's original containment semantics and hierarchy.	open	D Kelsey, IBM UK			1st July 05	

Figure 1. An example of a simple Excel “bug-tracking” representation.

To make the “SoftwareQualityControl to Bugzilla file” global transformation we proceed in three steps. Indeed, this transformation is in reality a composition of three transformations:

- from SoftwareQualityControl to Bugzilla
- from Bugzilla to XML
- from XML to Bugzilla XML file (i.e. XML to Bugzilla text)

These three steps are summarized in Figure 2.

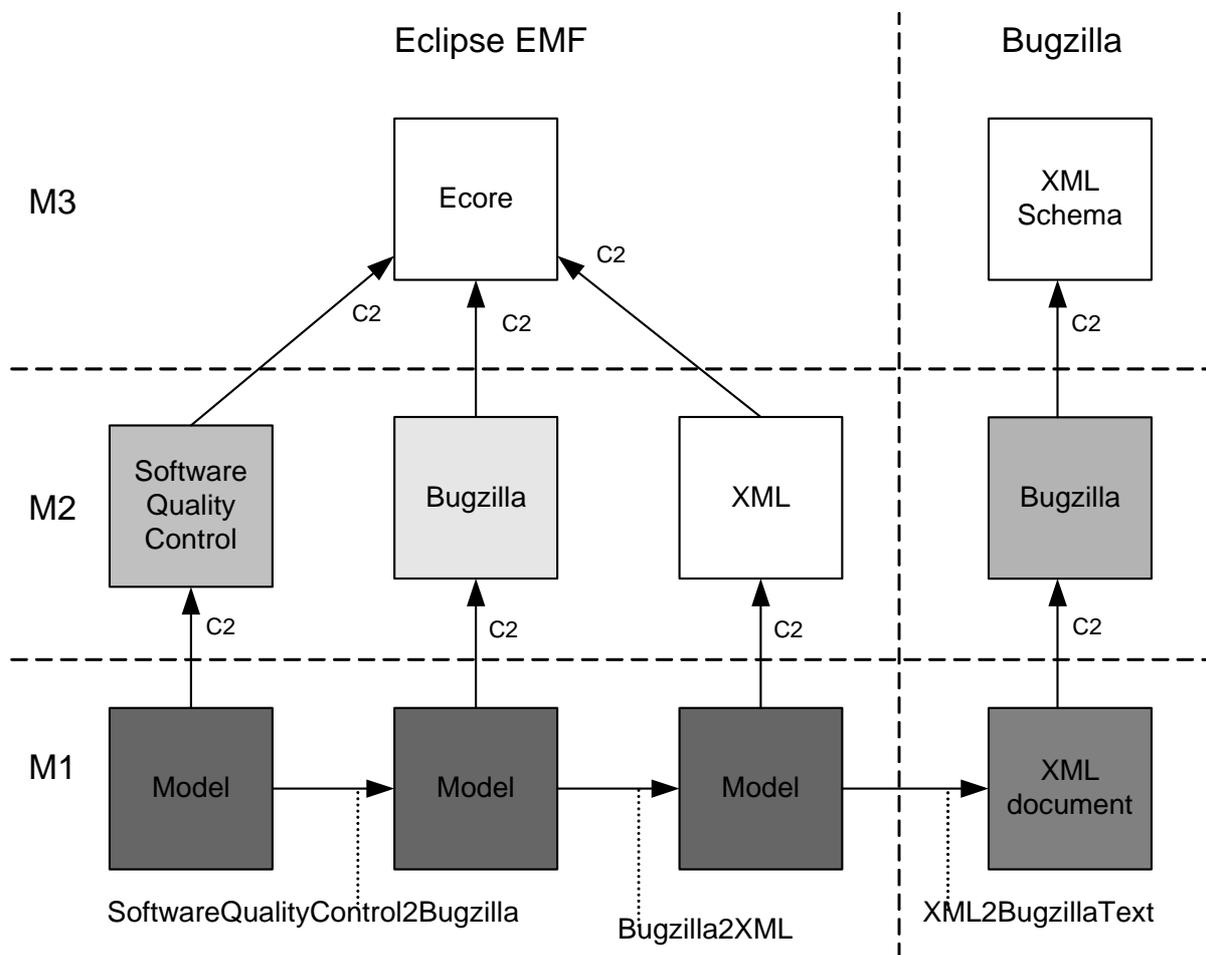

Figure 2. “Software Quality Control to Bugzilla file” transformation’s overview

	Software Quality Control to Bugzilla file	Date 02/08/2005

1.2. Metamodels

The transformation is based on the “SoftwareQualityControl” metamodel which describes a simple structure to manage software quality controls and more especially bug tracking. The metamodel considered here is described in Figure 3 and provided in Appendix I in km3 format. Note that we present in this documentation the current version of this metamodel that has been created for our particular example: it could be improved in order to allow handling several other types of quality control.

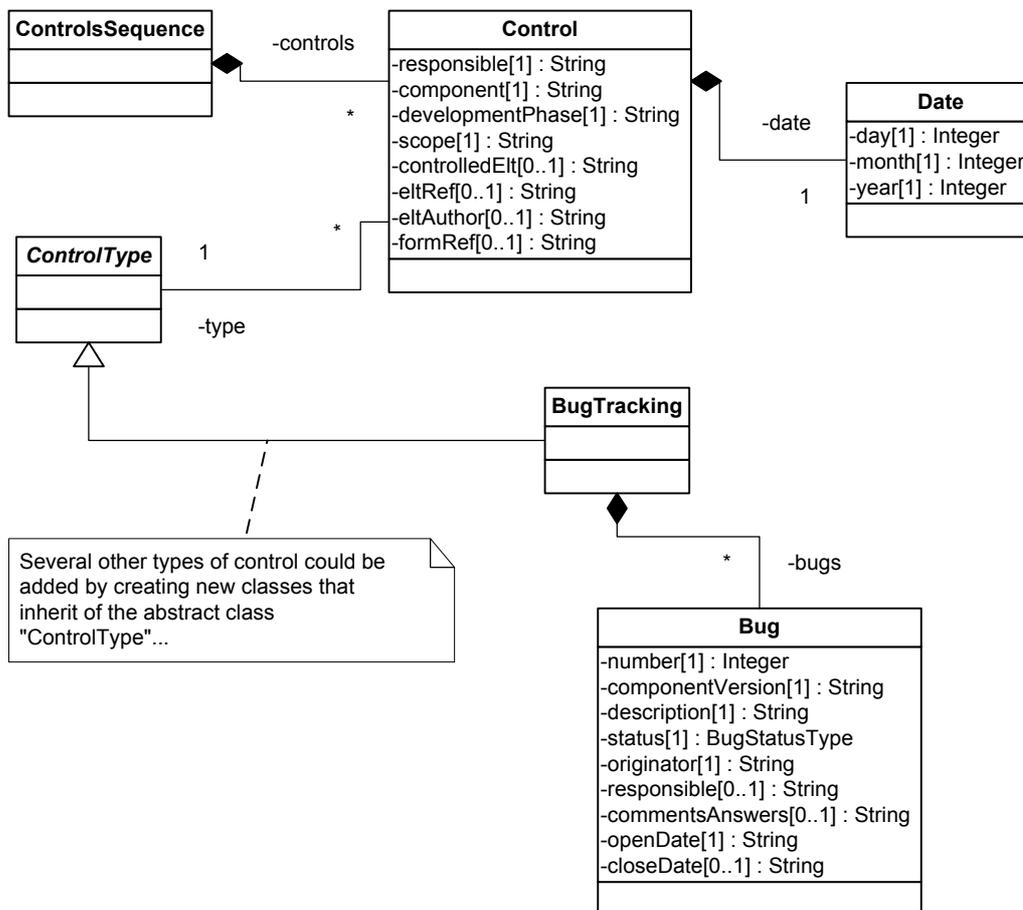

Figure 3. The SoftwareQualityControl metamodel

A “SoftwareQualityControl” model is composed of several *Control* elements. Each *Control* is defined by specific information about the component and the element which are concerned, about the person who is responsible for the control, the date, etc. The main information is the type of the control. It determines what kind of actions has been performed and consequently what kind of data has been saved. In the case of our example, we only create *BugTracking* type but it could have a lot of other control types. In this type, the control consists of a set of *Bug* elements in which each *Bug* is identified by a unique number. A *Bug* is characterized by several specific fields such as its description, its status...

The transformation is also based on the “Bugzilla” metamodel. Bugzilla is a free “defect-tracking” or “bug-tracking” system originally developed by the Mozilla Foundation. A huge database allows it to store a big amount of information about a lot of bugs. These data are too complex to be easily handled by SQL requests. However, it is possible to use a Perl script to import/export bugs’ data in a simpler XML format. The data in XML files conforms to a simple DTD [3].

The simple Bugzilla metamodel considered here is directly inspired by this DTD. It is described in Figure 4 and provided in Appendix II in km3 format.

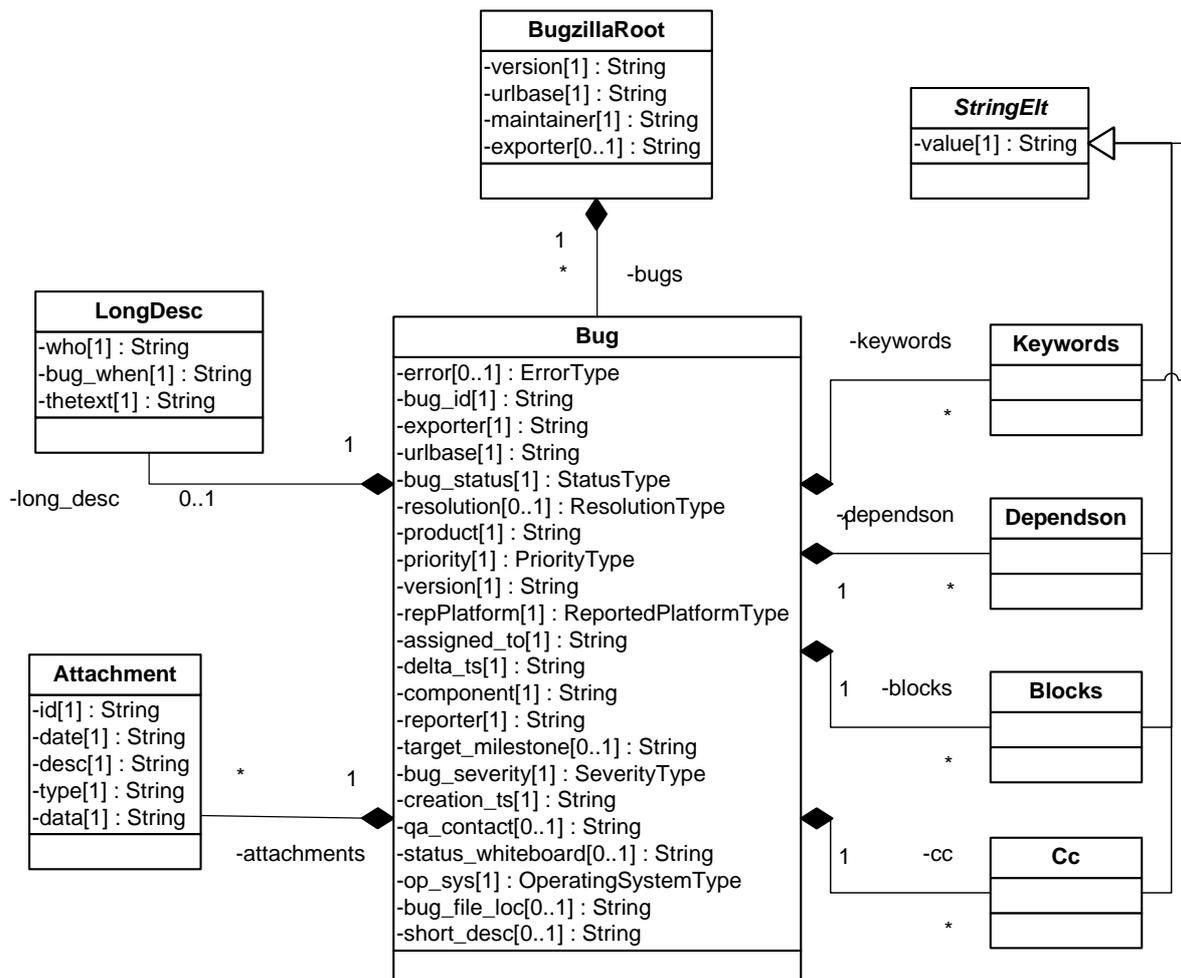

Figure 4. The Bugzilla metamodel

A Bugzilla model is a set of *Bug* elements. Each *Bug* is identified by an “id” string and contains much information about the bug itself but also about the people who deals with it, the software product that is concerned with, etc.

	ATL TRANSFORMATION EXAMPLE	Hugo Brunelière hugo.bruneliere@gmail.com
	Software Quality Control to Bugzilla file	Date 02/08/2005

The last metamodel used by this transformation is a simple XML metamodel which is necessary to export models into XML files. This metamodel is presented in Figure 5 and provided in Appendix III in km3 format.

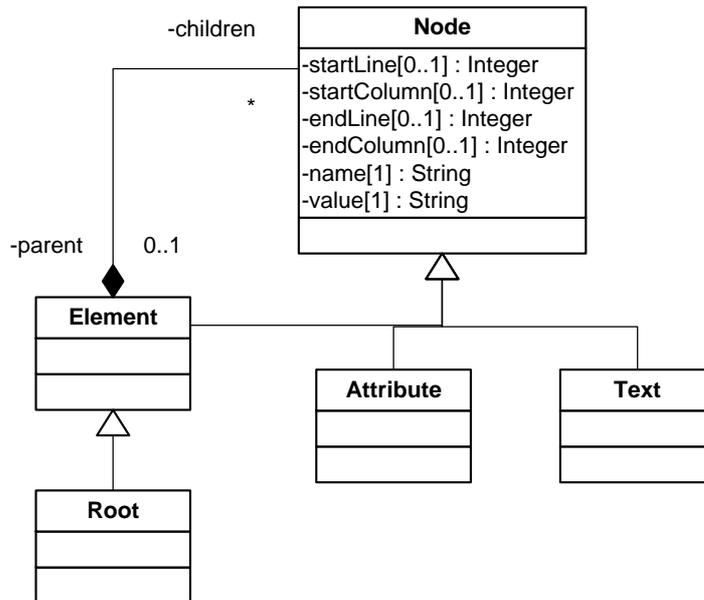

Figure 5. A simple XML metamodel

Each element of an XML document is a *Node*. The root of a document is a *Root* element which is an *Element* in our metamodel. Each *Element* can have several children (nodes) that can be other *Element*, *Attribute* or *Text* elements. An *Element* is usually identified by its name and defined by its children. An *Attribute* is characterized by its name and its value whereas a *Text* is only assimilated to a single value.

1.3. Rules Specification

The input of the global transformation is a model which conforms to the SoftwareQualityControl metamodel (described in Figure 3); the output is a Bugzilla XML file whose content conforms to a simple Bugzilla DTD [3]. The input Bugzilla model of the second transformation is the output Bugzilla model generated by the first transformation. The input XML model of the third transformation is the output XML model engendered by the second transformation.

1.3.1. SoftwareQualityControl to Bugzilla

These are the rules to transform a SoftwareQualityControl model into a Bugzilla model:

- For each *SoftwareQualityControl!BugTracking* element, a *Bugzilla!BugzillaRoot* element is created. It will be linked to the corresponding *Bugzilla!Bug* elements that will be generated during the transformation by the following rule.
- For each *SoftwareQualityControl!Bug* element, a *Bugzilla!Bug* element and a *Bugzilla!LongDesc* element are engendered. The attributes of these two generated elements are correctly initialized in this rule.

1.3.2. Bugzilla to XML

These are the rules to transform a Bugzilla model into an XML model:

- For the root *Bugzilla!BugzillaRoot* element, the “bugzilla” *XML!Root* element is created. The required *XML!Attribute* elements are also generated and added as children of this “bugzilla” *XML!Root* element.
- For each *Bugzilla!Bug* element, a “bug” *XML!Element* element is engendered and set as a child of the “bugzilla” *XML!Root* element. All the necessary *XML!Attribute*, *XML!Element* and *XML!Text* elements are also created and added as children of this “bug” *XML!Element* element.
- For each *Bugzilla!Keywords* element, a “keywords” *XML!Element* element and its child's *XML!Text* element are generated.
- For each *Bugzilla!Dependson* element, a “dependson” *XML!Element* element and its child's *XML!Text* element are created.
- For each *Bugzilla!Blocks* element, a “blocks” *XML!Element* element and its child's *XML!Text* element are engendered.
- For each *Bugzilla!Cc* element, a “cc” *XML!Element* element and its child's *XML!Text* element are generated.
- For each *Bugzilla!LongDesc* element, a “long_desc” *XML!Element* element and its children's *XML!Element* and *XML!Text* elements are generated.
- For each *Bugzilla!Attachment* element, an “attachment” *XML!Element* element and its children's *XML!Element* and *XML!Text* elements are generated.

	ATL TRANSFORMATION EXAMPLE	Hugo Brunelière hugo.bruneliere@gmail.com
	Software Quality Control to Bugzilla file	Date 02/08/2005

1.3.3. XML to Bugzilla XML file (i.e. XML to Bugzilla text)

There are no rules defined for this step but only an ATL query (and the associated ATL helpers) that allows generating a valid and well-formed Bugzilla XML text file from an XML model. The aim of this query is to extract each of the elements that compose the input XML model into an output XML file. Look at the “ATL Code” following section to get more details about this ATL query.

1.4. ATL Code

There is one ATL file coding a transformation for each of the three steps previously detailed. In this part we will present and describe more precisely the ATL code associated to each implemented transformation.

1.4.1. SoftwareQualityControl2Bugzilla

The ATL code for the “SoftwareQualityControl2Bugzilla” transformation consists of 1 helper and 2 rules.

The *convertStatus* helper returns the Bugzilla!StatusType value corresponding to the SoftwareQualityControl!BugStatusType value passed in argument.

The rule *BugTracking2BugzillaRoot* allocates a Bugzilla!BugzillaRoot element only if a BugTracking element is encountered in the input SoftwareQualityControl model. This generated Bugzilla!BugzillaRoot element will be linked, thanks to a “resolveTemp(...)” method’s call, to the corresponding Bugzilla!Bug elements that will be created by the following rule during the transformation.

The rule *Bug2Bug* allocates a Bugzilla!Bug element and a Bugzilla!LongDesc element for each SoftwareQualityControl!Bug element of the input model. The attributes of the generated elements are simply valued in the rule, if necessary, by traversing the input model and by thus recovering the sought values.

```

1.4.2. Bugzilla2XML

The ATL code for the “Bugzilla2XML” transformation consists of 7 helpers and 8 rules.

All the helpers have a quite similar function:

- The *getStringErrorValue* helper returns the string value corresponding to the Bugzilla!ErrorType passed in argument.
- The *getStringBugStatusValue* helper returns the string value corresponding to the Bugzilla!bugStatusType passed in argument.
- The *getStringResolutionValue* helper returns the string value corresponding to the Bugzilla!ResolutionType passed in argument.
- The *getStringPriorityValue* helper returns the string value corresponding to the Bugzilla!PriorityType passed in argument.
- The *getStringRepPlatformValue* helper returns the string value corresponding to the Bugzilla!ReportedPlatformType passed in argument.
- The *getStringSeverityValue* helper returns the string value corresponding to the Bugzilla!SeverityType passed in argument.
- The *getStringOperatingSystemValue* helper returns the string value corresponding to the Bugzilla!OperatingSystemType passed in argument.

Each implemented rule follows the same principle: an XML!Element (with some associated other XML!Element, XML!Attribute or XML!Text elements) is allocated for each element of the Bugzilla model. These generated XML elements are correctly linked from the ones to the others (thanks to “resolveTemp(...)” method’s calls) in order to construct an XML model whose content conforms to the simple Bugzilla DTD [3].

As an example, the *BugzillaRoot2Root* rule allocates a “bugzilla” XML!Element and three or four XML!Attribute elements (one of the corresponding attributes is optional in the Bugzilla metamodel), which are children of the XML!Element, for each BugzillaRoot element of the input Bugzilla model. This “bugzilla” XML!Element will be linked, thanks to a “resolveTemp(...)” method’s call, to the “bug” XML!Element elements that will be created to represent bugs by the *Bug2Bug* rule...

	Software Quality Control to Bugzilla file	Date 02/08/2005

1.4.3. XML2BugzillaText

The ATL code for this transformation consists in 4 helpers and 1 query.

Contrary to rules that are implemented to generate a model from another model, a query allows calculating output text files from an input model (see [4]). This is the reason why we need to use queries for this type of transformation: generating an XML file from an XML model. The implemented query gets the XML!Root of the XML model and calls the *BugzillaFile* helper on it. It recovers the string value returned by this helper (corresponding to the generated XML text) and writes it into an XML file located in the path passed in argument. The parsing of all input model's elements is recursively made from the *BugzillaFile* helper.

The *BugzillaFile* helper returns a string which is composed of the required XML file's header and of the Bugzilla XML file's content. This content is generated by the *toString2* helper called on the XML!Root element of the XML model.

There are three *toString2* helpers with different contexts. The XML!Attribute one simply returns the name and the value of an attribute in the correct string format. The XML!Text one only returns the string value contained in a text node. The XML!Element one returns the valid and well-formed content of the output XML file by parsing recursively all the elements of the input XML model (note that it sometimes calls the XML!Attribute and XML!Text *toString2* helpers).

```

1  query XML2Text = XML!Root.allInstances()
2      ->asSequence()
3      ->first().BugzillaFile().writeTo('C:\\... path to be completed before using the
4  transformation ...\\BugzillaXMLfileExample.xml');
5
6  helper context XML!Root def: BugzillaFile() : String =
7      '<?xml version="1.0"?>' + '\n' + self.toString2('');
8
9  helper context XML!Element def: toString2(indent : String) : String =
10     let na : Sequence(XML!Node) =
11         self.children->select(e | not e.oclIsKindOf(XML!Attribute)) in
12     let a : Sequence(XML!Node) =
13         self.children->select(e | e.oclIsKindOf(XML!Attribute)) in
14     indent + '<' + self.name +
15     a->iterate(e; acc : String = '' |
16         acc + ' ' + e.toString2()
17     ) +
18     if na->size() > 0 then
19         '>'
20         + na->iterate(e; acc : String = '' |
21             acc +
22             if e.oclIsKindOf(XML!Text) then
23                 ''
24             else
25                 '\r\n'
26             endif
27             + e.toString2(indent + ' ')
28         ) +
29         if na->first().oclIsKindOf(XML!Text) then
30             '</' + self.name + '>'
31         else
32             '\r\n' + indent + '</' + self.name + '>'
33         endif
34     else
35         '/>'

```

III. XML metamodel in KM3 format

```

-- @name XML
-- @version 1.1
-- @domains XML
-- @authors Peter Rosenthal (peter.rosenthal@univ-nantes.fr)
-- @date 2005/06/13
-- @description This metamodel defines a subset of Extensible Markup Language (XML)
and particular XML document. It describes an XML document composed of one root
node. Node is an abstract class having two direct children, namely ElementNode and
AttributeNode. ElementNode represents the tags, for example a tag named xml:
<xml></xml>. ElementNodes can be composed of many Nodes. AttributeNode represents
attributes, which can be found in a tag, for example the attr attribute: <xml
attr="value of attr"/>. ElementNode has two sub classes, namely RootNode and
TextNode. RootNode is the root element. The TextNode is a particular node, which
does not look like a tag; it is only a string of characters.

package XML {
  abstract class Node {
    attribute startLine[0-1] : Integer;
    attribute startColumn[0-1] : Integer;
    attribute endLine[0-1] : Integer;
    attribute endColumn[0-1] : Integer;
    attribute name : String;
    attribute value : String;
    reference parent[0-1] : Element oppositeOf children;
  }

  class Attribute extends Node {}

  class Text extends Node {}

  class Element extends Node {
    reference children[*] ordered container : Node oppositeOf parent;
  }

  class Root extends Element {}
}

package PrimitiveTypes {
  datatype Boolean;
  datatype Integer;
  datatype String;
}

```
